Plan

1st issue:

• To do :

- A python code: implementation and optimization of SVM using GA.
- A report briefly explaining SVM and its uses, the issue of Hyperparameters Optimization (*also known as Hyperparameters Tuning*) and how you approached this issue using GA (the length of the report should be between 1000 and 1500 words. You are encouraged to add tables and figures if needed).

2nd issue:

To do :

- A python code: implementation of Monte-Carlo simulation and Sobol sensitivity analysis for SVM robustness assessment.
- A report briefly explaining and discussing the approach you implemented (the length of the report should not exceed 1000 words. You are encouraged to add tables and figures if needed).

3rd issue:

• To do :

- A literature report discussing and explaining one or more approaches for mitigating the impact of measurement uncertainties on SVM performance. You can either propose an idea or discuss an approach that already exists in the literature (the length of the report should not exceed 1000 words. You are encouraged to add tables and figures if needed).

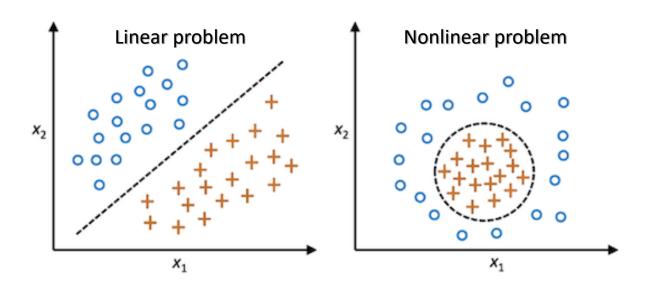

Introduction

The best way to introduce support vector machines (SVMs) is to consider the simple task of binary classification:

- the exchange rate of a currency will move up or down based on economic data.
- the decision to grant or deny a loan to a customer based on personal financial information.
- Predicting product conformity or non-conformity based on operating parameters.

Being a supervised learning algorithm, the focus of SVM is to learn from a dataset and try to generalize and make correct predictions on new data

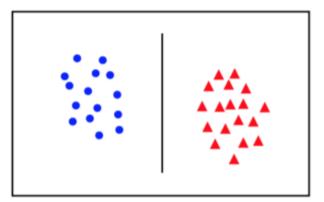

SVM

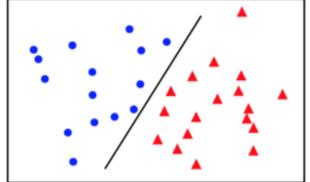

Arts Institute of the Arts electrology et Métiers

Linear SVM

Let $B_a = \{\{x_n, y_n\} \in \mathbb{R}^d \times \{-1, 1\}\}_{n=1...N}$ be a set of labeled learning examples.

The points $\{x_n, y_n\}$ are linearly separable if there is a hyperplane that correctly separates the two classes' data.

The objective of SVM is to learn a decision function f(x), such that:

$$f(x_n) \begin{cases} > 0 & si \quad y_n = 1 \\ < 0 & si \quad y_n = -1 \end{cases}$$

equivalently $y_n f(x_n) > 0$ for any correctly predicted example.

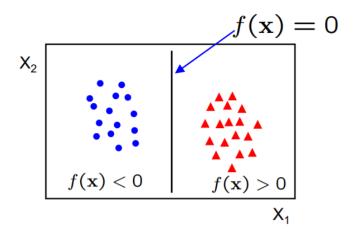

Arts restricts of rectionary et Métiers

Decision function

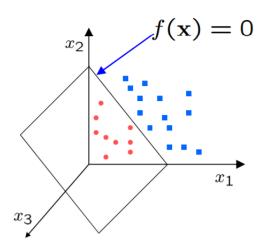

The expression for the decision function is:

$$f(\mathbf{x}) = \mathbf{w}^{\top} \mathbf{x} + b$$

- w is the normal vector to the hyperplane, and b the bias
- w is known as the weight vector.

Hyperplane in 2D = Line

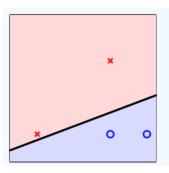

Hyperplane in 3D = Plan

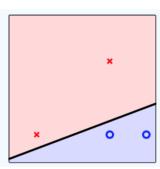

The hyperplane is the set of points x_n such that : $\mathbf{w}^T \mathbf{x_n} + \mathbf{b} = \mathbf{0}$

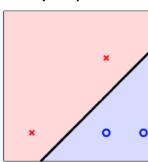

Arts Institute of et Métiers

Separating hyperplane

There are an infinite number of lines to separate data that are linearly separable.

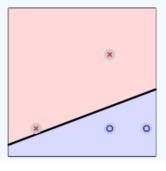

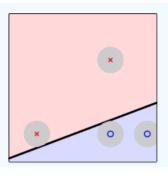

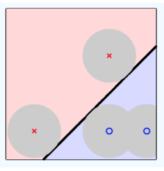

Which one to choose?:

The SVM chooses the hyperplane that most tolerates the noise in the training

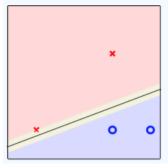

data

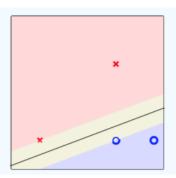

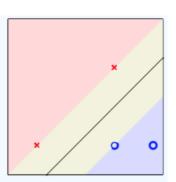

This results in a maximal margin between the two classes.

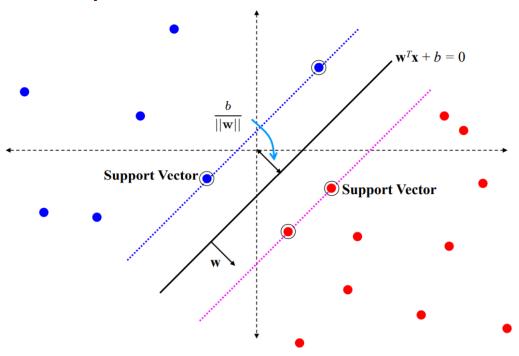

Arts Institute of technology et Métiers

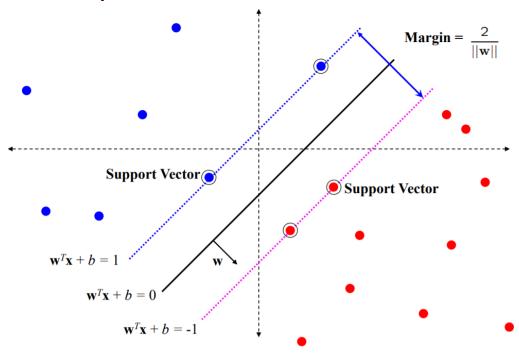

Summary of SVM concepts

- The decision function is defined by : $f(x_n) = w^T x_n + b$
- The hyperplane is the set of points $\{x_n\}$ that satisfy: $\mathbf{w}^T \mathbf{x_n} + \mathbf{b} = 0$
- Support vectors are the closest data points to the hyperplane. They influence the position and orientation of the hyperplane.

Arts Institute of technology et Métiers

Summary of SVM concepts

- The support vectors define two hyperplanes $\{H^+, H^-\}$.
- These support vectors satisfy the following equalities :
 - For the set of $\mathbf{x}_+ \in \mathbf{H}^+$: $\mathbf{w}^T \mathbf{x}_+ + \mathbf{b} = \mathbf{1}$
 - For the set of $\mathbf{x}_{-} \in \mathbf{H}^{-}$: $\mathbf{w}^{T}\mathbf{x}_{-} + \mathbf{b} = -1$
- The margin is therefore defined as the distance between H^+ and H^- along the unit vector $\frac{\vec{w}}{\|w\|}$:

$$Margin = \frac{2}{\|w\|}$$

Arts Institute of technology et Métiers

Linear SVM formulation

The objective of SVM is to maximize the margin; this can be formulated as an optimization problem :

$$\begin{aligned} max & \frac{1}{\|w\|} \\ s. t & y_i(w^T.x_i + b) \ge 1 & \forall i = 1, ..., N \\ & y_i \in \{-1,1\} \\ & w \in \mathbb{R}^d; b \in \mathbb{R} \end{aligned}$$

The quadratic formulation equivalent to this formulation:

$$min \quad \frac{1}{2}w^{T}.w$$

$$s.t \quad y_{i}(w^{T}.x_{i}+b) \geq 1 \qquad \forall i=1,...,N$$

$$y_{i} \in \{-1,1\}$$

$$w \in \mathbb{R}^{d}; b \in \mathbb{R}$$

This is a quadratic optimization problem subject to linear constraints, so there is a unique minimum (a unique vector w).

Arts restricte of et Métiers

Formulation de SVM linéaire

The quadratic formulation equivalent to this formulation:

$$min \quad \frac{1}{2}w^{T}.w$$

$$s.t \quad y_{i}(w^{T}.x_{i}+b) \geq 1 \qquad \forall i = 1,...,N$$

$$y_{i} \in \{-1,1\}$$

$$w \in \mathbb{R}^{d}; b \in \mathbb{R}$$

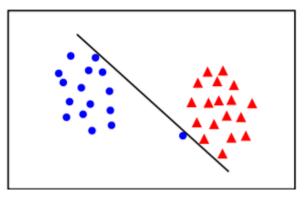

With the help of programming languages (e.g. python) we could solve this optimization problem and find the values of \mathbf{w} and \mathbf{b} .

The prediction of a new data x_n is done by evaluating the sign of the decision function $f(x_n)$:

- IF $\mathbf{f}(\mathbf{x_n}) = \mathbf{w^T}\mathbf{x_n} + \mathbf{b} < 0 \rightarrow \text{negative class } (y_n = -1)$
- IF $f(x_n) = \mathbf{w}^T x_n + \mathbf{b} > 0 \rightarrow \text{positive class } (y_n = +1)$

Arts Institute of the Metiers et Métiers

Limitations of linear SVM

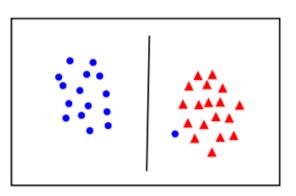

The points can be separated linearly, but the margin is very narrow.

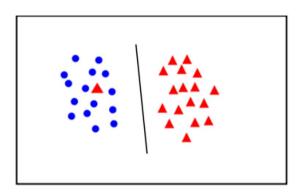

SVM fails to find a model that perfectly separates the data.

A very noise-sensitive model!

Algorithm does not converge!

What if we accept that some examples are on the wrong side of the hyperplane?

Better generalization of the model on new data.

Soft margin

For some non-linearly separable datasets, a linear separator would still give good results.

Condition: accept that some examples do not respect the constraint.

Problem: the current formulation of SVM does not allow this (hard margin).

Solution:

- Relax the constraints :
 - accept that the margin is crossed.
 - accept that some examples are on the wrong side of the hyperplane.
- Penalize these relaxations in the function to be optimized.

Soft margin

To penalize slacking, a slack variable ξ_n is associated with each learning example (x_n, y_n) .

New constraint::

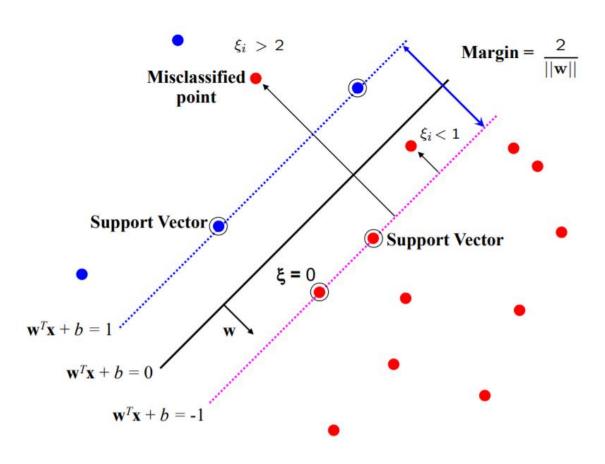

$$y_n\left(\mathbf{w}^{\mathrm{T}}\mathbf{x}_{\mathrm{n}}+\mathbf{b}\right)>1-\xi_n$$

 ξ_n informs how much an example (x_n,y_n) violates the constraint :

- IF $\xi_n = 0$ the example respects the constraint.
- IF $\xi_n > 1$ the example is misclassified.
- IF $0 < \xi_n < 1$ the example is well classified but has crossed the margin.

Arts Institute of technology et Métiers

Soft margin

New objective:

We want $\sum \xi_n$ to be minimal!

Arts Institute of rachnology et Métiers

Soft margin

The **new formulation** of soft-margin SVM is as follows:

$$\begin{aligned} \min & \quad \frac{1}{2} ||w||^2 + C \sum_{i=1}^{N} \xi_i \\ s.t & \quad y_i(w^T.x_i + b) \ge 1 - \xi_i \\ \xi_i \ge 0 & \quad \forall i = 1, ..., n \end{aligned}$$

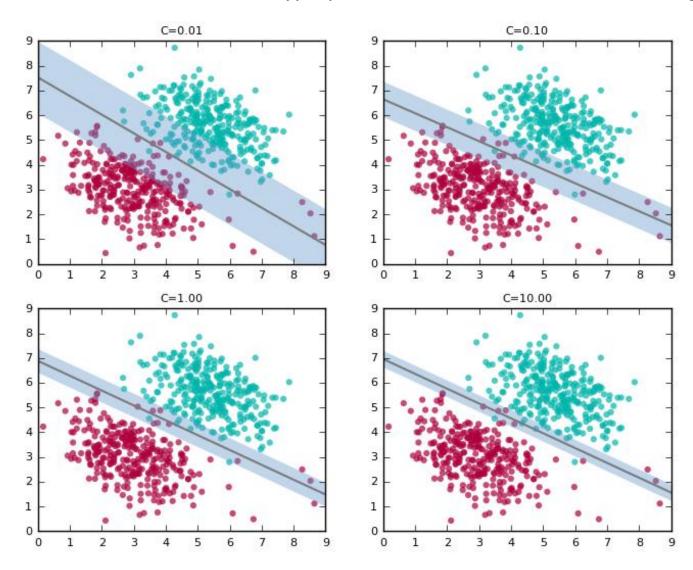

- Each constraint can be satisfied if ξ_n is large enough.
- **C** is a regularization parameter that handles the tradeoff between a maximum margin and constraint relaxation :
 - A small value of C allows constraints to be easily ignored → large margin
 - A large value of C makes constraints hard to ignore → narrow margin
- This is still a quadratic optimization problem and there is a unique minimum.
 Note that there is only one hyperparameter*, C.

^{*} a hyperparameter is a parameter whose value is used to control the learning process. Its value is defined before starting the learning process.

Arts leatitate of recharged et Métiers

Soft margin

Illustration of the influence of the hyperparameter C on the width of the margin:

Non-linear separator

Basic idea: if you can't separate **positives** from **negatives** in a low-dimensional space using a hyperplane, then project all the data into a higher-dimensional space where you can separate them.

Apply to the data a transformation $\phi\colon \mathbb{R}^d \to \mathbb{R}^{\widetilde{d}}$ to a higher-dimensional space :

$$z_n = \boldsymbol{\phi}(x_n)$$

After transforming the data, we solve the SVM problem in this new redescription space.

$$min \quad \frac{1}{2}\widetilde{w}^T.\widetilde{w}$$

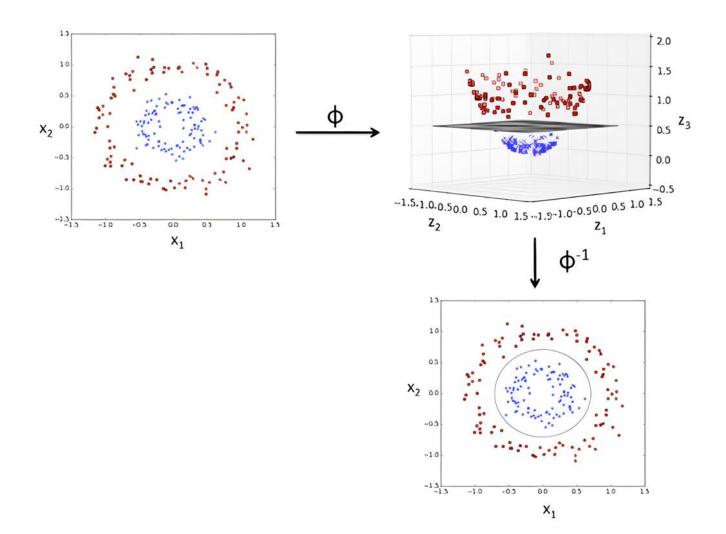

$$s.c \quad y_n(\widetilde{w}^T.\mathbf{z}_n + b) \ge 1 \qquad \forall n = 1, ..., N$$

$$y_n \in \{-1,1\}$$

Non-linear separator

In this way, we can separate the two classes represented in the new space by a linear hyperplane that becomes a nonlinear decision boundary if we project it back onto the original feature space.

Arts rechnology et Métiers

kernel trick

Let's consider the following transformation:

$$\phi \colon \mathbb{R}^2 \to \mathbb{R}^3$$

$$\phi(x) = \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} \to \begin{pmatrix} x_1^2 \\ x_2^2 \\ \sqrt{2}x_1x_2 \end{pmatrix}$$

Scalar product:

$$\phi(x). \phi(x') = (x_1^2 \quad x_2^2 \quad \sqrt{2}x_1x_2) \begin{pmatrix} x'_1^2 \\ x'_2^2 \\ \sqrt{2}x'_1x'_2 \end{pmatrix}$$

$$= x_1^2 x'_1^2 + x_2^2 x'_2^2 + 2x_1 x'_1 x_2 x'_2$$

$$= (x_1 x'_1 + x_2 x'_2)^2 = (x^T. x')^2$$

In this case, the function $(x^T, x')^2$ allows us to avoid having to compute the scalar product of two examples explicitly, saving us a lot of time.

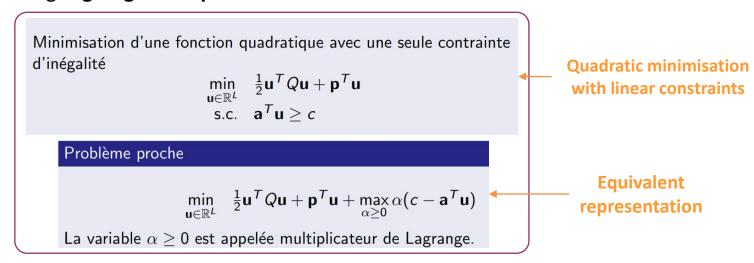

The goal is to take advantage of this trick in the case of SVMs, in order to reduce the computation time in the nonlinear cases.

Kernel trick - dual formulation

In order to take advantage of this trick, called the kernel trick, the SVM formulation must be reformulated so that the scalar product appears.

This can be done using Lagrange multipliers:

In the case of **SVM**:

Minimiser
$$\frac{1}{2}\mathbf{w}^T\mathbf{w}$$

 $s.c.$ $y_n(\mathbf{w}^T\mathbf{x}_n + b) \ge 1$ $\forall n = 1, ..., N$

$$\mathcal{L}(b, \mathbf{w}, \alpha) = \frac{1}{2}\mathbf{w}^T\mathbf{w} + \sum_{n=1}^N \alpha_n (1 - y_n(\mathbf{w}^T\mathbf{x}_n + b))$$

$$\mathcal{L}(b, \mathbf{w}, \alpha) = \frac{1}{2}\mathbf{w}^T\mathbf{w} - \sum_{n=1}^N \alpha_n y_n \mathbf{w}^T\mathbf{x}_n - b \sum_{n=1}^N \alpha_n y_n + \sum_{n=1}^N \alpha_n$$
Dual formulation

Kernel trick - dual formulation

$$\mathcal{L}(b, \mathbf{w}, \alpha) = \frac{1}{2} \mathbf{w}^T \mathbf{w} + \sum_{n=1}^{N} \alpha_n (1 - y_n (\mathbf{w}^T \mathbf{x}_n + b))$$

$$\mathcal{L}(b, \mathbf{w}, \alpha) = \frac{1}{2} \mathbf{w}^T \mathbf{w} - \sum_{n=1}^{N} \alpha_n y_n \mathbf{w}^T \mathbf{x}_n - b \sum_{n=1}^{N} \alpha_n y_n + \sum_{n=1}^{N} \alpha_n$$

- We have transformed a constrained quadratic programming problem into... an unconstrained quadratic programming problem.
- This formulation has an important advantage in the case of SVMs (cf. Kernel trick)

Interpretation:

- \mathcal{L} must be minimized with respect to the primal variables (b, w) and maximized with respect to the dual variables α_n .
- If the constraint is satisfied, i.e., $1-y_n\left(\mathbf{w}^T\mathbf{x}_n+\mathbf{b}\right)\leq 0$ then $\alpha_n=0$, except for the support vectors (because increasing α_n minimizes $\boldsymbol{\mathcal{L}}$ which is contrary to the objective).
- If the constraint is violated: α_n will grow to maximize, and $\mathcal{L}(b, w)$ will decrease so that the constraints are satisfied.

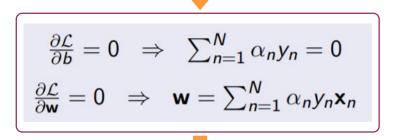

Kernel trick – minimisation % (b,w)

$$\mathcal{L}(b, \mathbf{w}, \alpha) = \frac{1}{2} \mathbf{w}^T \mathbf{w} + \sum_{n=1}^{N} \alpha_n (1 - y_n (\mathbf{w}^T \mathbf{x}_n + b))$$

$$\mathcal{L}(b, \mathbf{w}, \alpha) = \frac{1}{2} \mathbf{w}^T \mathbf{w} - \sum_{n=1}^{N} \alpha_n y_n \mathbf{w}^T \mathbf{x}_n - b \sum_{n=1}^{N} \alpha_n y_n + \sum_{n=1}^{N} \alpha_n$$

minimisation % (b,w)

We replace the values obtained in the Lagrangian and we obtain

$$\mathcal{L}(\alpha) = -\frac{1}{2} \sum_{n=1}^{N} \sum_{m=1}^{N} y_n y_m \alpha_n \alpha_m \mathbf{x}_n^T \mathbf{x}_m + \sum_{n=1}^{N} \alpha_n$$

A formulation to maximize that depends only on the dual variable $lpha_n$

Arts Institute of Technology et Métiers

Kernel trick - dual formulation

The optimization problem can then be written as:

$$\begin{array}{ll}
\min_{\alpha \in \mathbb{R}^{N}} & \frac{1}{2} \sum_{n=1}^{N} \sum_{m=1}^{N} y_{n} y_{m} \alpha_{n} \alpha_{m} \Phi(\mathbf{x}_{n})^{T} \Phi(\mathbf{x}_{m}) - \sum_{n=1}^{N} \alpha_{n} \\
s.c. & \sum_{n=1}^{N} y_{n} \alpha_{n} = 0 \\
& \alpha_{n} \geq 0
\end{array}$$

Thus, we have the following decision function:

$$\left[\sum_{\xi \in \mathcal{S}} g(\mathbf{x}) = sign \left(\sum_{\alpha_n^* > 0} y_n \alpha_n^* \mathbf{x}_n^\mathsf{T} \mathbf{x} + b^* \right) \right]$$

- Only the support vectors are needed to predict the class of a new data, as they define the separating hyperplane.
- The calculation of the α_n is done using a solver.
- This new formulation allows to benefit from the kernel trick.

Kernel trick - dual formulation

In the previous formulation (for learning and decision), the only calculation that is performed in the redescription space is a scalar product.

$$\phi(x).\phi(x')$$

The idea is to find a function that computes both the transformation and the scalar product.

$$K_{\phi}(x.x') = \phi(x).\phi(x')$$

 K_{ϕ} is a kernel function.

A number of kernel functions are known, including:

• Polynomial kernel
$$K(x, x') = (\alpha x^{\top} \cdot x' + \lambda)^d$$

 $K(x, x') = \exp\left(-\frac{\|x - x'\|^2}{2}\right)$

• RBF kernel
$$K(x,x') = \exp\left(-\frac{\|x-x'\|^2}{2\sigma^2}\right)$$

• Laplacian kernel $K(x,x') = \exp\left(-\frac{\|x-x'\|^2}{\sigma}\right)$

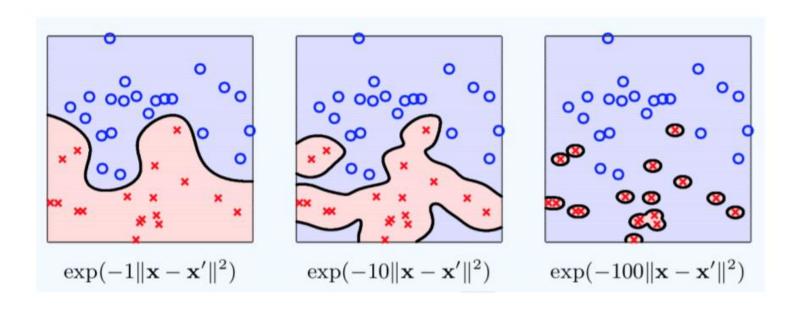

• Laplacian kernel
$$K(x,x') = \exp\left(-\frac{\|x-x'\|}{\sigma}\right)$$

• Rational kernel
$$K(x,x')=1-rac{\|x'-x\|^2}{\|x'-x\|^2+\sigma}$$

Arts Institute of technology et Métiers

Kernel trick - Gaussian Kernel (RBF)

Illustration of classification by RBF kernel

SVM

Conclusion

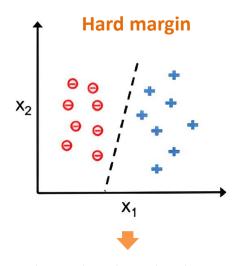

- Does not allow the extraction of a comprehensible/interpretable model.
- Unsuitable for mining very large volumes of data.
- Kernel selection: no solution at the moment except by trial and error.
- Provides a global optimum, but what does it really mean for a real dataset?
- To do machine learning, you need to understand the algorithm you are using. Clearly, a good understanding of SVM is not easy.

Summary

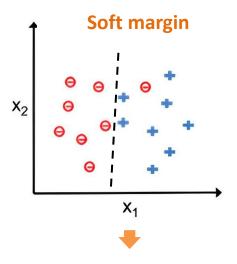

For a first use of SVM, you have to keep in mind that:

SVM is used for binary classification problems

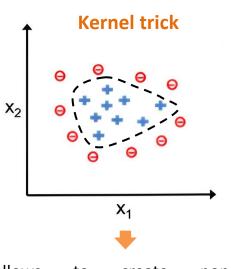

Only works when the data can be separated linearly.

No hyperparameters defined in the formulation.

Allows to tolerate classification errors during the training phase.

The **hyperparameter C** for controlling the margin width, has to be optimized.

Allows to create non-linear separations.

The **Kernel function** and **its parameters** are the hyperparameters to be optimized.

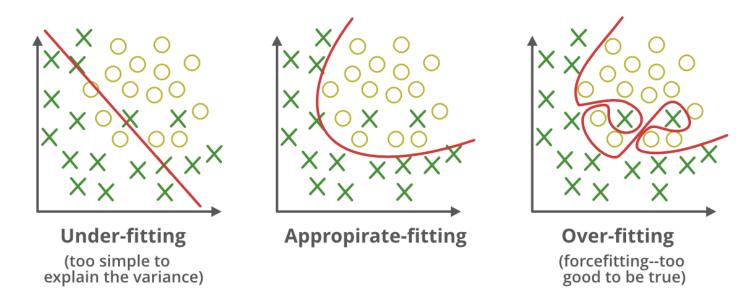

In general, both the **C-hypeparameter** and the **kernel function** are incorporated in the same SVM formulation.

Hyperparameters

The aim of **hyperparameters** is to control the over-fitting and under-fitting of the model.

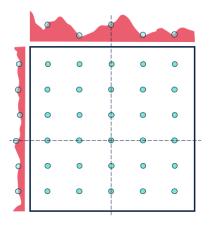

Optimal hyperparameters often differ for different datasets.

To get the best hyperparameters the following steps are followed:

- 1. For each proposed hyperparameter setting the model is evaluated.
- 2. The hyperparameters that give the best model are selected.

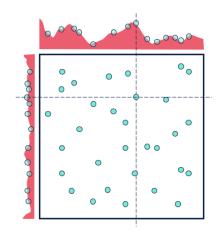

Hyperparameters Search

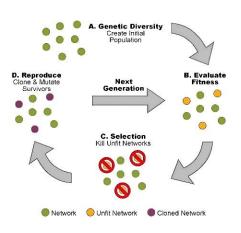

Grid search involves specifying a list of possible hyperparameter values that you want to test.

The algorithm will then train models with all possible combinations of the provided hyperparameter values and evaluate the performance of each trained model using a specified metric.

Random search

Instead of providing a list of hyperparameter values, you will provide statistical distributions of hyperparameter values from which you want the optimization algorithm to test values.

Genetic algorithm

One of the most widely used metaheuristic algorithms is the genetic algorithm (GA), which is based on the evolutionary idea that individuals (hyperparameters in this case) with the highest potential for survival and adaptation to the environment are more likely to survive and pass on their qualities to future generations.

Arts institute of et Métiers LCFC

Genetic Algorithm (GA)

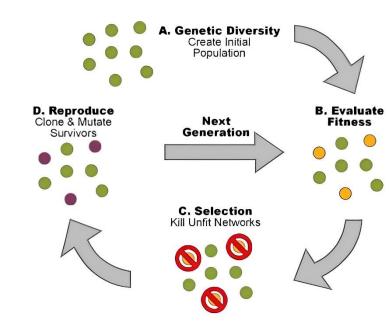

The algorithm starts by randomly generating many different initial sets of hyperparameter values.

The algorithm then trains models with these randomly generated hyperparameter values and assesses them with a defined evaluation metric.

The sets of hyperparameter values that perform the worst on the evaluation metric are **thrown out**, and **new values are generated** to replace them based on the values that performed best on the evaluation metric.

In this way genetic algorithms try to mimic the human evolution to some extent.

However, to successfully implement GA, its basic structure and steps must be clearly defined.

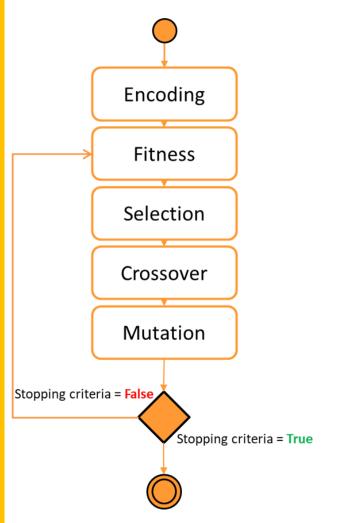

Genetic Algorithm (GA)

The algorithm works by first creating a random population of a fixed size.

The main loop of the algorithm is repeated for a **fixed number** of iterations or until a termination criteria is reached.

<u>Encoding and population initialization</u>: One of the most critical decisions that significantly affects the performance of a genetic algorithm while implementing it, is deciding the representation to use in order to represent the candidate solutions (individuals).

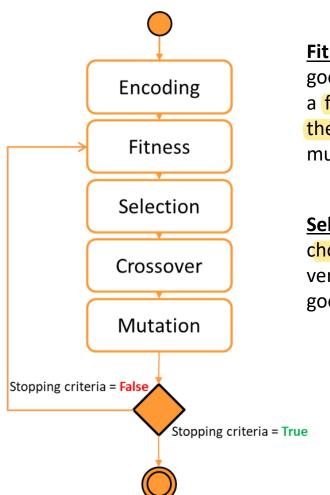

Two well-known representations are:

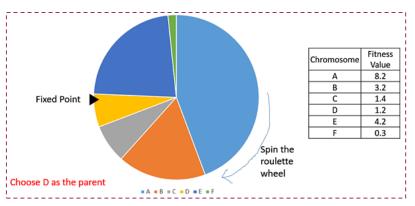

Genetic Algorithm (GA)

<u>Fitness</u>: Through any GA, it is necessary to be able to evaluate how good a potential solution is, compared to other solutions. To do so, a <u>fitness function</u> is defined. The fitness values are then <u>used for the selection of individuals (parents)</u>, on which crossover and mutation operations will be applied.

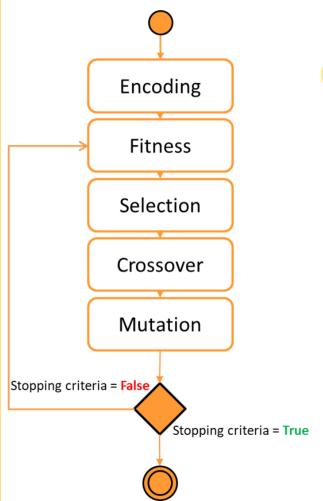

<u>Selection</u>: Selection operation in a genetic algorithm consists of choosing individuals (parents) for reproduction. Parent selection is very important to the convergence of the genetic algorithm (GA), as good parents generate and yield better and fitter solutions.

Roulette Wheel Selection

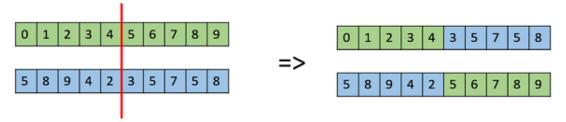

Genetic Algorithm (GA)

<u>Crossover</u>: By this operator, individuals (parents) share information by crossing their genotypes to create better individuals (children).

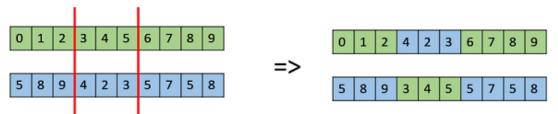

One Point Crossover

In this one-point crossover, a random crossover point is selected and the tails of its two parents are swapped to get new off-springs.

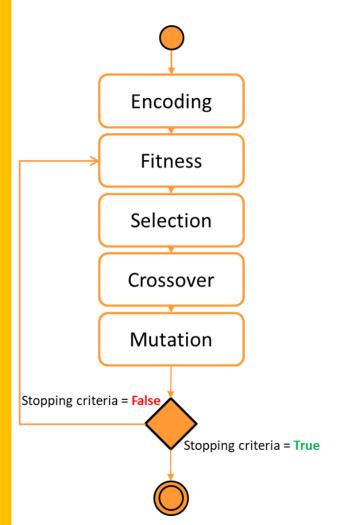

Multi Point Crossover

Multi point crossover is a generalization of the one-point crossover wherein alternating segments are swapped to get new off-springs.

Genetic Algorithm (GA)

<u>Mutation</u>: Mutation may be defined as a small random modification in the chromosome to get a new solution. It is used to introduce diversity in the genetic population and to release from local minima.

• Bit Flip Mutation

In this bit flip mutation, we select one or more random bits and flip them. This is used for binary encoded GAs.

0 1 1 0 1 0 0 1 0 =>	0 0	1	0 0	0 1	0 0	1	0
----------------------	-----	---	-----	-----	-----	---	---

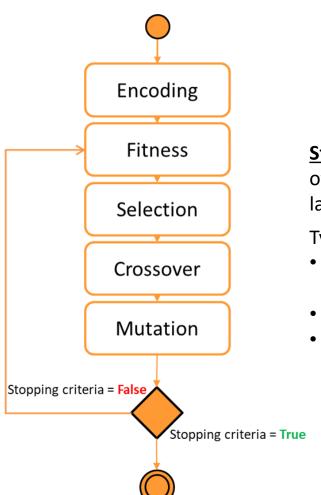

Swap Mutation

In swap mutation, we select two positions on the chromosome at random, and interchange the values. This is common in permutation based encodings.

Genetic Algorithm (GA)

<u>Stopping criteria</u>: GA progresses very quickly with better solutions over the course of a few iterations, but this tends to saturate in the later stages where the improvements are very small.

Typically, we keep one of the following termination conditions.

- When there has been no improvement in the population for X iterations.
- When we reach an absolute number of generations.
- When the value of the objective function has reached a certain predefined value.

Arts institute of technology et Métiers

Robustness?

The ability of a system to maintain its performance, despite changes in operating conditions or the presence of uncertainties related to its parameters or components.

A product or a process whose performance is **little affected by the variation** of the conditions in which it operates is said to be **robust**.

Robustness is, according to **G. Taguchi**, the essential component of the quality of a product.

The principle of robust engineering is to tackle the variability experienced in production, not by eliminating the causes, which is generally an impossible or too costly solution, but by seeking a design/modeling that limits its effects.

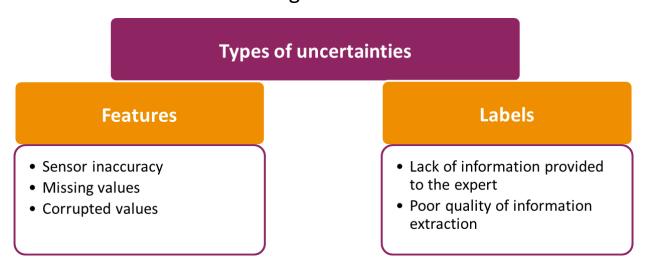

Arts leating of racehology et Métiers

Robustness of an ML model

Robustness is also desired in Machine Learning, where we seek to implement models that are robust to uncertainties.

Measurable data for machine learning and data mining are usually imprecise, incomplete, or noisy.

Machine learning systems must deal with imperfect data and are therefore expected to reason under conditions of ignorance.

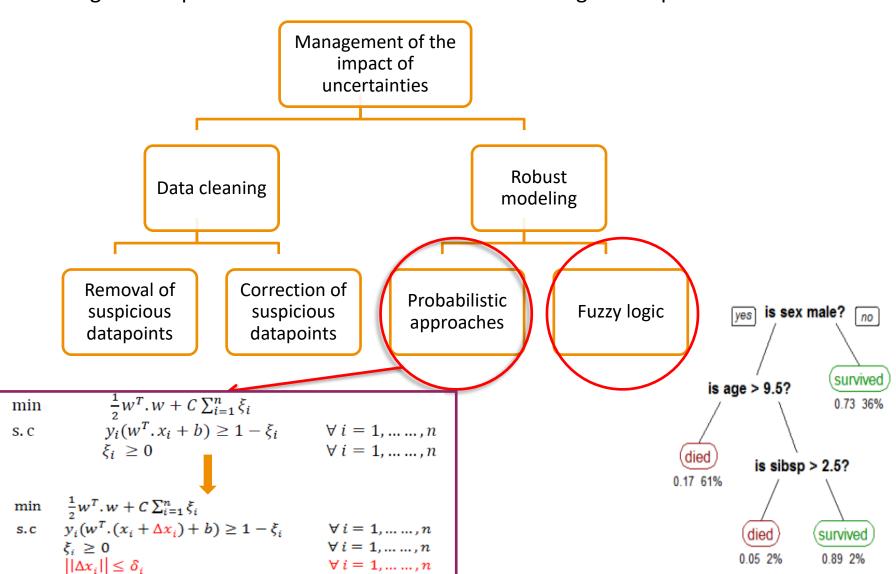

Impact of uncertainties:

- Decreases the performance of the classifiers.
- Increases the amount of data needed for training.

Robustness of an ML model

To manage the impact of uncertainties on machine learning techniques.

Robustness of an ML model

A first objective is not to control the impact of uncertainties on the performance of machine learning techniques, but to :

- 1. Quantify the impact of these uncertainties on the performance of classifiers.
- 2. Identify the parameters that contribute most to this impact.

How to?

Monte Carlo simulation to calculate the impact of measurement uncertainties on prediction accuracy

Arts institute of et Métiers

Monte Carlo simulation

The term Monte Carlo refers to a family of algorithmic methods that use random processes to calculate an approximate numerical value.

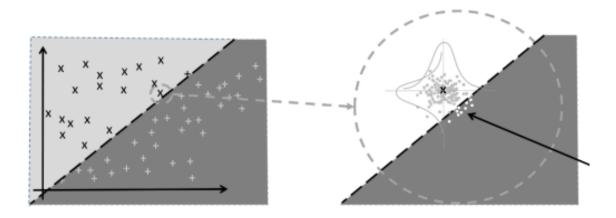

The main purpose of Monte Carlo simulation is to perform a large number of experiments on random samples and then draw conclusions about the model outputs.

Monte Carlo simulations are considered effective mathematical analysis methods used to solve complex engineering problems because of their ability to handle large numbers of random variables, different types of distributions, and highly nonlinear engineering models.

Arts institute of et Métiers LCFC

Monte Carlo simulation

Illustration of a data point subject to measurement uncertainties:

The approach to evaluate the impact of uncertainties on the predictive performance of a classifier consists in:

- 1. Set up a predictive model.
- 2. Compare the prediction of the model on a clean validation/test set to its prediction on noisy validation/test sets.

Monte-Carlo for impact quantification

A procedure for evaluating the robustness of classifiers; **SVM** as a case study.

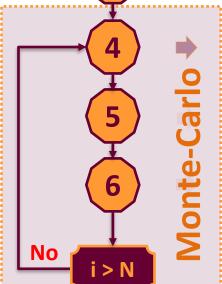

1. Preprocess the dataset: data split, data normalization, ...

2. Train the SVM model using the training set.

3. Generate 1000 (N) random Gaussian noises.

- 4. Noise the validation/test set with the ith noise.
- 5. Assess the prediction accuracy of SVM.
- 6. Store the found result.

7. Quantify the impact of uncertainties.

- 2. Identify the parameters that contribute most to this impact.

How to?

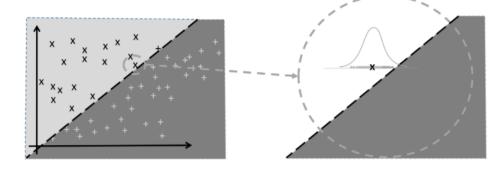

SOBOL sensitivity analysis consisting of dividing the variance of the output into fractions that can be attributed to the inputs.

Arts Institute of the Arts of

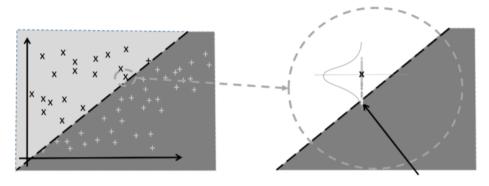

Introduction

The Monte Carlo simulation results do not identify the parameters uncertainties that have the most impact on the SVM accuracy.

In the first figure, it is shown that the uncertainties of the first parameter have no effect on the classification of the data point;

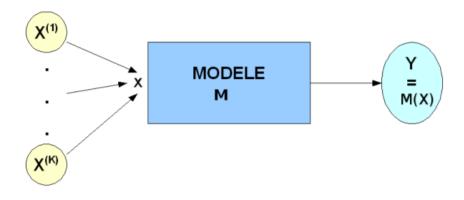

on the other hand, the uncertainties associated with the second parameter can lead to a misclassification of this data point.

The objective of the SOBOL sensitivity analysis is to answer this question and identify the parameters that contribute most to the drop in prediction accuracy.

Arts institute of ethnology et Métiers

Sobol analysis (SA)

Aims of SA

- Uncertainty analysis: uncertainties, variabilities on $X_i \Rightarrow \text{Effects on } Y$
- Sensitivity analysis: which X_i are the most influential on Y

Model = black box (analytical form may be unknown)

$$Y = M(X_1, \dots, X_d)$$

Our goal: is to measure the overall influence of the input factors X_i on Y

- over a range of variation of X_i
- with the minimum of assumptions on the model
- by integrating the interactions between the X_i

Arts Institute of et Métiers

Sobol indices

Sobol analysis is based on **variance decomposition** techniques to provide a quantitative measure of the contributions of the input to the output variance.

The decomposition of the output variance in a Sobol sensitivity analysis uses the same principle as the classical analysis of variance in a factorial design, allowing the output variance to be represented as follows:

$$V = \sum_{i=1}^{p} V_i + \sum_{1 \le i \le j \le p}^{p} V_{ij} + \dots + V_{1...p}$$

Where:

V: The total variance of the model output.

 V_i : The first order contribution of the i^{th} parameter of the model.

 V_{ij} : The contribution of the interaction of the i^{th} and j^{th} parameters.

Arts institute of ethnology et Métiers

Sobol indices

Based on this decomposition, Sobol defines:

First order sensitivity indices

$$S_i = \frac{V_i}{V}$$

A quantitative measure of the contribution of the main effect of the input parameter X_i to the variance of the output.

Higher order sensitivity indices

$$S_{ij} = \frac{V_{ij}}{V}$$
; $S_{ijk} = \frac{V_{ijk}}{V}$

A quantitative measure of the contribution of the interaction of the ith and jth parameters to the variance of the output.

How to interpret the Sobol indices?

Being all positive, the larger the index (close to 1), the more important the parameter impact is.

Arts Institute of technology et Métiers

Sobol indices

The number of sensitivity indices thus constructed, from order 1 to order p, is equal to $(2^p - 1)$.

When the number of input variables p is too large, the number of sensitivity indices increases dramatically. Estimation and interpretation of all these indices quickly becomes impossible.

To solve this problem, Homma and Saltelli introduced "Sobol total effect" indices, which express the total sensitivity of the variance Y to a variable Xi.

The total sensitivity index S_{T_i} is defined as the sum of the contribution caused by X_i and its interactions -of any order- with any other input variable.

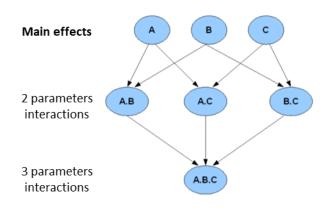

$$S_{T_i} = \sum_{k \neq i} S_k$$

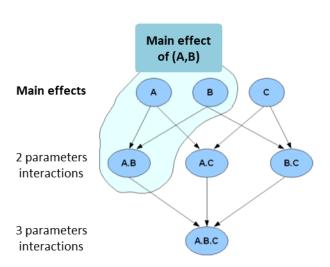

Where #i represents all sets containing index i

Illustration of the Sobol indices

For a system defined by 3 parameters:

Arts institute of echnology et Métiers

Estimation of the Sobol indices

Exact calculation of Sobol indices is often impossible, since:

- large dimensional integrals are used,
- in machine learning we are faced with models where the analytical form of the model is not known.

One way to estimate the Sobol indices is to apply a sampling approach based on Monte-Carlo simulation.

Let's take two samples A and B

$$A = \begin{pmatrix} x_{A,1;1} & \dots & x_{A,1;d} \\ \dots & \dots & \dots \\ x_{A,N;1} & \dots & x_{A,N;d} \end{pmatrix}$$

$$B = \begin{pmatrix} x_{B,1;1} & \dots & x_{B,1;d} \\ \dots & \dots & \dots \\ x_{B,N;1} & \dots & x_{B,N;d} \end{pmatrix}$$

$$ightarrow C_i = \ egin{pmatrix} X_{A,1;1} & \dots & X_{B,1;i} & \dots & X_{A,1;d} \ \dots & \dots & \dots & \dots \ X_{A,N;1} & \dots & X_{B,N;i} & \dots & X_{A,N;d} \ i = 1,\dots,d \end{pmatrix}$$

Arts institute of et Métiers et Métiers

Estimation of the Sobol indices

Once C_i is defined, we use the model at disposition to compute the different outputs:

$$A = \begin{pmatrix} x_{A,1;1} & \dots & x_{A,1;i} & \dots & x_{A,1;d} \\ \dots & \dots & \dots & \dots \\ x_{A,N;1} & \dots & x_{A,N;i} & \dots & x_{A,N;d} \end{pmatrix} \xrightarrow{\mathcal{M}} Y_A = \begin{pmatrix} y_{A,1} \\ \vdots \\ y_{A,N} \end{pmatrix}$$

$$C_{i} = \begin{pmatrix} X_{A,1;1} & \cdots & X_{B,1;i} & \cdots & X_{A,1;d} \\ \cdots & \cdots & \cdots & \cdots \\ X_{A,N;1} & \cdots & X_{B,N;i} & \cdots & X_{A,N;d} \end{pmatrix} \xrightarrow{\mathcal{M}} Y_{C_{i}} = \begin{pmatrix} y_{C_{i},1} \\ \vdots \\ y_{C_{i},N} \end{pmatrix}$$

$$B = \begin{pmatrix} X_{B,1;1} & \dots & X_{B,1;i} & \dots & X_{B,1;d} \\ \dots & \dots & \dots & \dots \\ X_{B,N;1} & \dots & X_{B,N;i} & \dots & X_{B,N;d} \end{pmatrix} \xrightarrow{\mathcal{M}} Y_B = \begin{pmatrix} y_{B,1} \\ \vdots \\ y_{B,N} \end{pmatrix}$$

- \Rightarrow Estimation of S_{T_i} using A and C_i
- \Rightarrow Estimation of S_i using B and C_i

Arts Institute of Arts Technology et Métiers

Estimation of the Sobol indices

Thus, we can estimate the first-order and total Sobol indices by:

$$\hat{S}_i = rac{\hat{V}_i}{\hat{V}} \,,$$

$$\hat{S}_{T_i} = rac{\hat{V}_{-(i)}}{\hat{V}}$$

where:

 $\hat{V} = \text{Total variance of the output}$

and:

$$\hat{V}_i = \frac{1}{N} \sum_{k=1}^{N} y_{B,k} (y_{C_i,k} - y_{A,k})$$

$$\hat{V}_{-(i)} = \frac{1}{N} \sum_{k=1}^{N} y_{A,k} (y_{A,k} - y_{C_i,k})$$

Project

Project – issue 2

- 1. How to quantify the impact of uncertainties on SVM accuracy?
- 2. How to identify the key parameters?

 Measurement uncertainties

 Manufacturing data

 Quality improvement

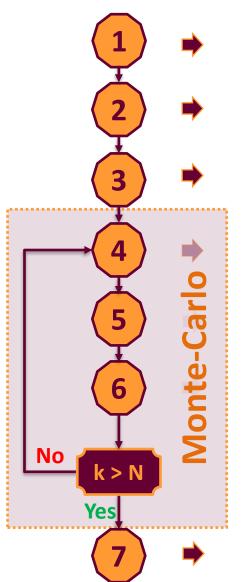

In this project, and by using the previous results found in the 1st part, you are going to focus on:

- ✓ The implementation of the Monte-Carlo simulation for the quantification of the uncertainties impact on SVM prediction accuracy.
- ✓ Implementing Sobol sensitivity analysis for estimating Sobol indices, i.e., the uncertainties of the parameters that have the most impact on the accuracy of the SVM.
- ✓ The analysis of the different results.

A step-by-step guide for the implementation of Monte-Carlo and Sobol analysis is provided in the following slides.

Monte-Carlo for impact quantification

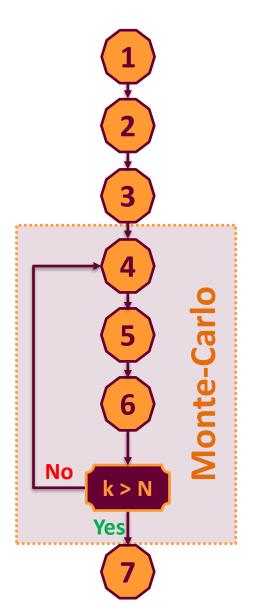

- 1. Preprocess the dataset: data split, data normalization, ...
- 2. Train the SVM model using the training set.
- 3. Generate 1000 (N) random Gaussian noises.
- 4. Noise the validation/test set with the k^{th} noise.
- 5. Assess the prediction accuracy of SVM.
- 6. Store the found result.

7. Quantify the impact of uncertainties.

Arts institute of et Métiers LCFC

Monte-Carlo for impact quantification

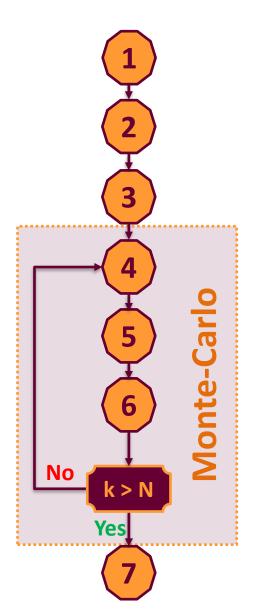

1. Preprocess the dataset: data split, data normalization, ...

- Import the dataset.
- Normalize (scale) the dataset : using the Min and Max values of the training set.
- Split the dataset into training, validation and test sets.

Monte-Carlo for impact quantification

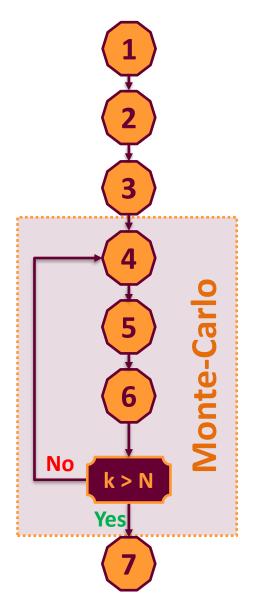

2. Train the SVM model using the training set.

optimal myperparameters round in the previous recture.

Monte-Carlo for impact quantification

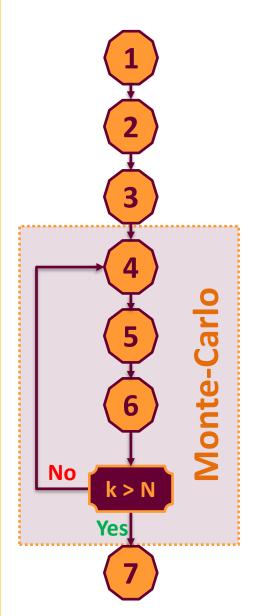

- Calculate the standard deviation σ_i of each parameter X_i (NB: the calculation must be made on the non normalized dataset)
- 3. Generate 1000 (N) random Gaussian noises. randomly following the gaussian distribution $N(0; \frac{2.5*\sigma_i}{100})$

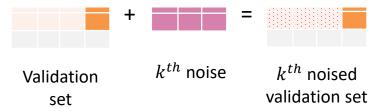

Monte-Carlo for impact quantification

• Add the k^{th} randomly generated matrice of noise to the validation set, with k in range(0,1000).

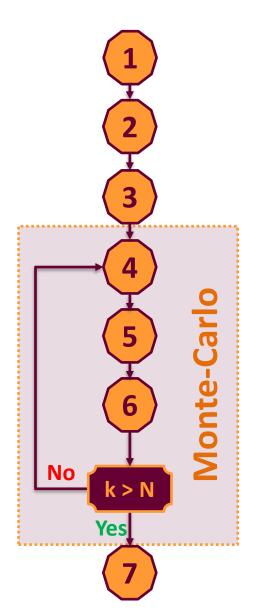

4. Noise the validation/test set with the k^{th} noise.

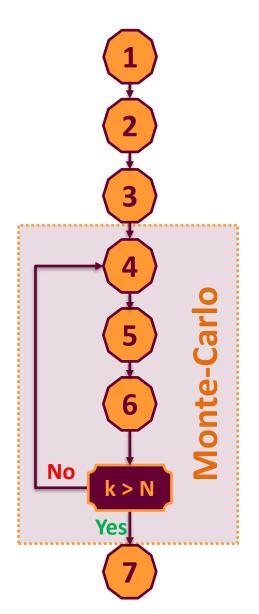

Monte-Carlo for impact quantification

- Normalize (scale) the k^{th} noised validation set: using the Min and Max values of the training set.
- By using the SVM model trained in step 2, calculate the prediction accuray of the k^{th} noised validation set.
- Calculate the **drop of accuracy** defined as the difference between the prediction accuracy of the validation set and
- 5. Assess the prediction accuracy of SVM.

Arts lastitute of et Métiers

Monte-Carlo for impact quantification

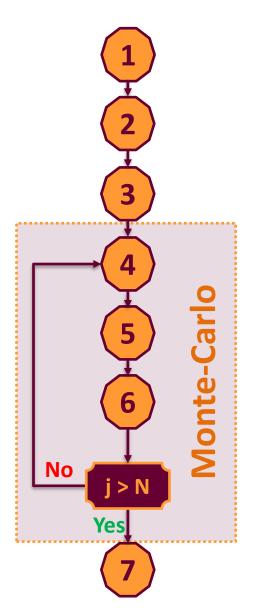

- Store the drop of accuracy somewhere.
- Check if k > N.

6. Store the found result

Monte-Carlo for impact quantification

• Calculate the mean of the drops of accuracy.

7. Quantify the impact of uncertainties.

Arts institute of et Métiers

Sobol indices

Goal:

Estimating Sobol indices \Rightarrow key parameters identification, i.e., identification of parameters' uncertainties with the most impacts.

Principle of Sobol analysis:

Dividing the output variance into fractions that can be attributed to the inputs.

How to?:

One of the ways to estimate Sobol indices is by using the Monte-Carlo simulation. The Monte-Carlo estimation consists of estimating:

- 1. the output expected value (E[Y]),
- 2. the output variance (V[Y]),
- 3. and two quantities (\hat{U}_i) and $(\hat{U}_{\sim i})$.

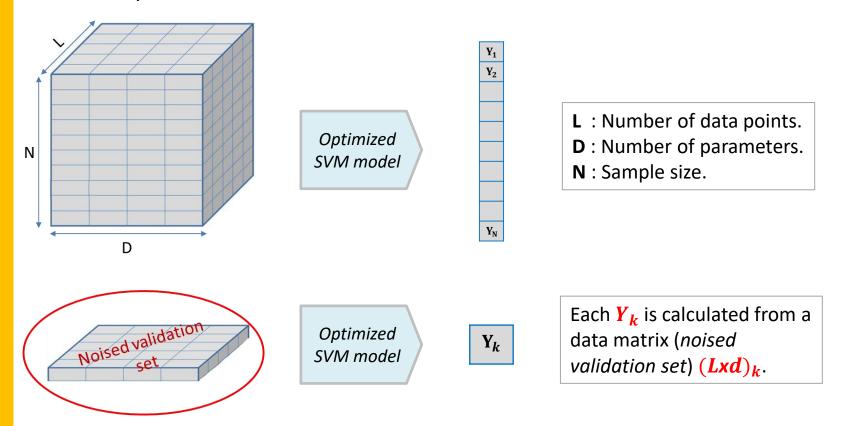

The estimation of these four quantities requires two N-samples.

Arts Institute Arts Cachadagy et Métiers

Step 0

In this step, the definition of the N-sample and of the output is given.

The N-sample in our case is: 1000 noised validation sets.

 Y_k = (SVM accuracy of initial validation set) – (SVM accuracy of the k^{th} noised validation set)

Arts Institute of the Arts Trachmology et Métiers

Step 1 – Expected value

Formula:

$$\hat{E} = E[Y] = \frac{1}{N} \sum_{k=1}^{N} f(x_{k1}, ..., x_{kp})$$

Interpretation:

In other words, you need to calculate the mean of all the Y_k . Good news !! You've already performed this in the first part of this project.

Arts fastitute of et Métiers

Step 2 – Expected value

Formula:

$$\hat{V} = V[Y] = \frac{1}{N} \sum_{k=1}^{N} f^{2}(x_{k1}, ..., x_{kp}) - \hat{E}^{2}$$

Interpretation:

The variance can be formulated as a function of the expected value. It is the difference between the sum of the squares of $\boldsymbol{Y_k}$ and the square of the expected value.

$$\widehat{V} = \frac{1}{N} \sum_{k=1}^{N} Y_k^2 - \widehat{E}^2$$

Step 3 – First order Sobol indices

The estimation of the first order Sobol sensitivity indices consists in estimating the quantity $\boldsymbol{V_i}$

$$V_i = V(E[Y|X_i]) = \underbrace{E[E[Y|X_i]^2]}_{U_i} - E[E[Y|X_i]]^2 = U_i - E[Y]^2$$

Sobol proposes to estimate the quantity U_i like a classical expected value but taking into account the conditionality to X_i by varying between the two calls to the function f (trained SVM model in our case) all the variables except the variable X_i . This requires two samples of the input variables.

$$\hat{\mathbf{U}}_{i} = \frac{1}{N} \sum_{k=1}^{N} f(x_{k1}^{(1)}, \dots, x_{k(i-1)}^{(1)}, x_{ki}^{(1)}, x_{k(i+1)}^{(1)}, \dots, x_{kp}^{(1)}). f(x_{k1}^{(2)}, \dots, x_{k(i-1)}^{(2)}, x_{ki}^{(1)}, x_{k(i+1)}^{(2)}, \dots, x_{kp}^{(2)})$$

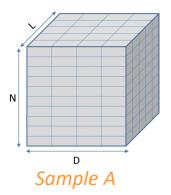

First order sensitivity indices can thus be calculated:

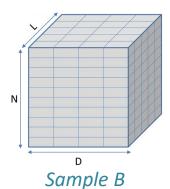

$$\hat{S}_i = \frac{\hat{U}_i - \hat{E}^2}{\hat{V}}$$

Step 3 – First order Sobol indices

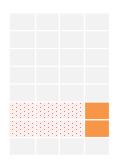

"Let's get practical and calculate the first order Sobol index of the first parameter X_1 !!"

1. Generate two 1000-samples of noised validation sets.

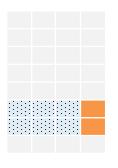

- Pick the k^{th} noised validation set from each sample.
- Create a third noised validation set from the two picked validation sets

 $A_k: k^{th}$ noised validation set from sample A

 $\boldsymbol{B_k}$: k^{th} noised validation set from sample B

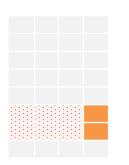

Inject all the parameters of B_k into A_k , except the first parameter X_1 .

Arts Institute Arts Company et Métiers

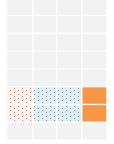

Step 3 – First order Sobol indices

- 2. Pick the k^{th} noised validation set from each sample.
- 3. Create a third noised validation set from the two picked validation sets

 $oldsymbol{B_k}$: k^{th} no

Inject all the parameters of \boldsymbol{B}_k into \boldsymbol{A}_k , except the first parameter \boldsymbol{X}_1 .

 $A_k: k^{th}$ noised validation set from sample A

B_k: kth noised validation set from sample B

C_k: kth generated noised validation set

- 4. Predict $A_k \ (= Y_{A_k})$ then $C_k \ (= Y_{C_k})$ using the optimized SVM model.
- 5. Multiply both prediction accuracies : $Y_{A_k} * Y_{C_k}$
- 6. Repeat steps 2, 3, 4 and 5 for k in range(0,1000).
- 7. Calculate the first order Sobol index of the first parameter X_1 .

$$\widehat{S_1} = \frac{(\frac{1}{N} \sum_{k=1}^{N} Y_{A_k} * Y_{C_k}) - \widehat{E^2}}{\widehat{V}}$$

8. Do the same previous steps for all the parameters X_i to calculate all first order Sobol indices.

Arts finitiate de l'enhancier et Métiers

Step 4 – Sobol total effect indices

The Sobol total effect indices can be estimated directly as follow:

$$S_{T_i} = 1 - \frac{V(E[Y|X_{\sim i}])}{V(Y)} = 1 - \frac{V_{\sim i}}{V}$$

Where $V_{\sim i}$ is the variance of the expected value of Y conditional on all variables except X_i . $V_{\sim i}$ is then estimated as V_i , except that instead of varying all the variables except X_i , we only vary only X_i .

$$V_{\sim i} = E[E[Y|X_{\sim i}]^2] - E[E[Y|X_{\sim i}]]^2 = U_{\sim i} - E[Y]^2$$

and:

$$\hat{U}_{\sim i} = \frac{1}{N} \sum_{k=1}^{N} f\left(x_{k1}^{(1)}, \dots, x_{k(i-1)}^{(1)}, x_{ki}^{(1)}, x_{k(i+1)}^{(1)}, \dots, x_{kp}^{(1)}\right) f\left(x_{k1}^{(1)}, \dots, x_{k(i-1)}^{(1)}, x_{ki}^{(2)}, x_{k(i+1)}^{(1)}, \dots, x_{kp}^{(1)}, \right)$$

Sobol Total-effect indices indices can therefore be calculated:

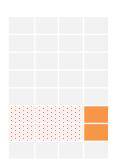

$$\hat{S}_{Ti} = 1 - \frac{\hat{U}_{\sim i} - \hat{E}^2}{\hat{V}}$$

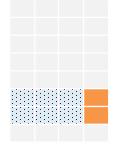

Arts institute of et Métiers LCFC

Step 4 – Sobol total effect indices

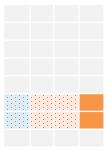

"We'll focus on the calculation of the Sobol total effect index of the first parameter X_1 !!"

- 1. Generate two 1000-samples of noised validation sets (same as in step 3).
- 2. Pick the $m{k^{th}}$ noised validation set from each sample (same as in step 3).
- 3. Create a third noised validation set from the two picked validation sets

Inject the first parameter of B_k into A_k .

 $A_k: k^{th}$ noised validation set from sample A

 $B_k: k^{th}$ noised validation set from sample B

C_k: kth created noised validation set

- 4. Predict $A_k \ (= Y_{A_k})$ then $\mathcal{C}_i \ (= Y_{\mathcal{C}_k})$ using the optimized SVM model.
- 5. Multiply both prediction accuracies : $Y_{A_k} * Y_{C_k}$
- 6. Repeat steps 2, 3, 4 and 5 for k in range(0,1000).
- 7. Calculate the Sobol total effect index the first parameter X_1 .

$$\widehat{S_{T_1}} = 1 - \frac{\left(\frac{1}{N}\sum_{k=1}^{N} Y_{A_k} * Y_{C_k}\right) - \widehat{E}^2}{\widehat{V}}$$

8. Do the same previous steps for all the parameters X_i to calculate all Sobol total effect indices.
